Summary

Program analysis framework:

Each TM compute some partially defined function: input is a string which is written on the tape at the start and output is a string which is written after halting of TM.

Given any nontrivial function property P we can search for algorithm for determining P for a function computed by any given TM.

Does this algorithm exists?

Given any nontrivial function property P we can search for algorithm for determining P for a function computed by any given TM.

Does this algorithm exists?

Rice's Theorem

For any nontrivial property P problem whether a function computed by given TM satisfies P is **undecidable**.

Summary

Auguste Kerckhoffs (19th century):

A cryptosystem should be secure even if everything about the system, except the **key**, is public knowledge.

It was reformulated (perhaps independently) by Claude Shannon as "the enemy knows the system". It is widely embraced by cryptographers, in opposition to **security through obscurity**.

In accordance with Kerckhoffs' law, the majority of civilian cryptography makes use of publicly-known algorithms. By contrast, ciphers used to protect classified government or military information are often kept secret.

Summary

So, what is NP class about?

So, what is NP class about?

⇒ We say $L \in NP$ iff there exists polynomial algorithm A such that

$$x \in L \Leftrightarrow \exists w : A(x, w) = 1$$

So, what is NP class about?

⇒ We say $L \in NP$ iff there exists polynomial algorithm A such that

$$x \in L \Leftrightarrow \exists w : A(x, w) = 1$$

⇒ We say $S \in \widetilde{NP}$ iff there exists polynomial algorithm A such that

$$(x, y) \in S \Leftrightarrow \exists w : A(x, y, w) = 1$$

So, what is NP class about?

⇒ We say $L \in NP$ iff there exists polynomial algorithm A such that

$$x \in L \Leftrightarrow \exists w : A(x, w) = 1$$

⇒ We say $S \in \widetilde{NP}$ iff there exists polynomial algorithm A such that

$$(x, y) \in S \Leftrightarrow \exists w : A(x, y, w) = 1$$

Deobfuscation is in \widetilde{NP}

Deobfuscation input: $O(P)$, solution: P .

So, what is NP class about?

Summary

Complexity theory:

⇒ Worst case complexity

Cryptography:

⇒ Almost every case complexity

Security proofs in classical cryptography:

If somebody can break given cryptosystem then he is also able to solve some computational problem with high every-case complexity.

Some examples of problems with **believed** high every-time complexity:

- ⇒ FACTORING: given $N = pq$ find p and q .
- ⇒ DISCRETE LOG: given a, N and $(a^x \bmod N)$ find x .
- ⇒ SUBSET SUM: given w_1, \dots, w_n and t determine whether exist $x_1, \dots, x_n \in \{0, 1\}$ such that $\sum x_i w_i = t$
- ⇒ Decomposition of multivariate polynomials
- ⇒ Some special linear codes decoding: given message x find nearest codeword.

Summary

So, what is Oblivious Transfer?

- ⇒ Two players Alice and Bob
- ⇒ Bob holds some information items x_1, \dots, x_n
- ⇒ Alice want to get x_i from Bob and at the same time keep i as a secret from Bob
- ⇒ Bob wanted to reveal not more than one item to Alice

And there are protocols achieving this goal!

Summary

So, what is Secret Multiparty Computation?

- ⇒ Several players A_1, \dots, A_k
- ⇒ Several input items x_1, \dots, x_n
- ⇒ Predefined function $F(x_1, \dots, x_n)$
- ⇒ Every player knows only **subset** of input set
- ⇒ Goal: to compute F in the way that nobody get more knowledge about x_1, \dots, x_n than just his subset and value of F

Examples: Millionaire problem, Electronic voting

Summary

Slide from Lecture 3 — your turn to explain.

General idea: to design an encoding such that it is possible to evaluate various operations over encrypted messages (and getting **encrypted** results) without decrypting them.

In particular encoding is called

- ⇒ **Additively homomorphic** if it is possible to compute $E(x + y)$ from $E(x)$ and $E(y)$
- ⇒ **Multiplicatively homomorphic** if it is possible to compute $E(xy)$ from $E(x)$ and $E(y)$
- ⇒ **Algebraically homomorphic** if it is both additive and multiplicative.

Summary

So, what is One-Way Functions and One-Way Permutations and Trap-Door Functions?

Informally:

⇒ One-Way Function:

- polynomially computable function
- but not polynomially reversible

⇒ One-Way Permutation:

- polynomially computable **bijection**
- but not polynomially reversible

⇒ Trap-Door Function: parametric function with such a description that:

- it is polynomially computable
- not polynomially reversible given only description
- but given explicit value of parameter is polynomially reversible!

Summary

So, what are Pseudo-Random Generators and Pseudo-Random Functions?

So, what are Pseudo-Random Generators and Pseudo-Random Functions?

Informally:

⇒ Pseudo-Random Generator is a family of functions such that:

- they compute mappings from \mathbb{B}^n to \mathbb{B}^m , $m > n$
- given a black-box access to representative of family it is computationally hard to distinguish it from truly random generator

⇒ Pseudo-Random Function is a function G such that:

- it computes a mapping from \mathbb{B}^n to $\{F : \mathbb{B}^m \rightarrow \mathbb{B}^k\}$, $k > m$
- given a black-box access random result of G it is computationally hard to distinguish whether it was generated by G or was randomly chosen from all functions ($\{F : \mathbb{B}^m \rightarrow \mathbb{B}^k\}$)

Summary

How can we define security of obfuscated program

⇒ Explicitly

- Define adversary task and require that it should be computationally difficult
- Disadvantage: there are a lot of threats and some of them are difficult to formulate in terms of computational problems

⇒ Implicitly

- Define ideal security model and require that our case is nearly as good as ideal one
- Disadvantage: Impossibility result by **[Barak et al.]**
